

SDG indicator metadata

(Harmonized metadata template - format version 1.0)

0. Indicator information

0.a. Goal

Goal 3: Ensure healthy lives and promote well-being for all at all ages

0.b. Target

Target 3.1: By 2030, reduce the global maternal mortality ratio to less than 70 per 100,000 live births

0.c. Indicator

Indicator 3.1.2: Proportion of births attended by skilled health personnel

0.d. Series

0.e. Metadata update

16 February 2021

0.f. Related indicators

Related to Target 3.1 on reducing maternal mortality, 3.2 on reducing neonatal mortality and 3.8 on achieving universal health coverage (coverage of essential health services)

0.g. International organisations(s) responsible for global monitoring

United Nations Children's Fund (UNICEF) and World Health Organization (WHO)

1. Data reporter

1.a. Organisation

United Nations Children's Fund (UNICEF) and World Health Organization (WHO)

2. Definition, concepts, and classifications

2.a. Definition and concepts

Definition:

Proportion of births attended by skilled health personnel (generally doctors, nurses or midwives but can refer to other health professionals providing childbirth care) is the proportion of childbirths attended by professional health personnel. According to the current definition (1) these are competent maternal and newborn health (MNH) professionals educated, trained and regulated to national and international standards. They are competent to: (i) provide and promote evidence-based, human-rights based, quality, socio-culturally sensitive and dignified care to women and newborns; (ii) facilitate physiological processes during labour and delivery to ensure a clean and positive childbirth experience; and (iii) identify and manage or refer women and/or newborns with complications.

2.b. Unit of measure

This indicator is reported in proportion (or percentage)

2.c. Classifications

An important aspect of this indicator is the reporting of categories of health providers at country level. Standard categories for the indicator include doctor, nurse and midwife. However, some additional categories are currently being reported by some countries. When that is the case, a process of verification is conducted in which the competency level of other categories of health care providers is assessed with national sources and in communication with national counterparts.

3. Data source type and data collection method

3.a. Data sources

National-level household surveys are the main data sources used to collect data for skilled health personnel. These surveys include Demographic and Health Surveys (DHS), Multiple Indicator Cluster Surveys (MICS), Reproductive Health Surveys (RHS) and other national surveys based on similar methodologies. Surveys are undertaken every 3 to 5 years. Data sources also include routine service statistics

Population-based surveys is the preferred data source in countries with a low utilization of childbirth services, where private sector data are excluded from routine data collection, and/or with weak health information systems. These surveys include Demographic and Health Surveys (DHS), Multiple Indicator Cluster Surveys (MICS), Reproductive Health Surveys (RHS) and other national surveys based on similar methodologies. In MICS, DHS and similar surveys, the respondent is asked about the last live birth and who helped during delivery for a period up to five years before the interview. The surveys are generally undertaken every 3 to 5 years.

Routine service/facility records is a more common data source in countries where a high proportion of births occur in health facilities and are therefore recorded. These data can be used to track the indicator on an annual basis.

3.b. Data collection method

UNICEF and WHO maintain a joint database on SDG 3.1.2 Proportion of births attended by skilled health personnel and collaborate to ensure quality and consistency of data sources. (mentioned above).

As part of the data harmonization process and interaction with countries an annual country consultation is conducted by UNICEF. During the country consultation SDG country focal points are contacted for updating and verifying values included in the database and for obtaining new data sources. New data sources are reviewed and assessed jointly with WHO. As part of the process, the national categories of skilled health personnel are verified. The reported data for some countries may include additional categories of trained personnel beyond doctor, nurse and midwife.

3.c. Data collection calendar

UNICEF/WHO database is updated on an annual basis. However, not all countries report new data on annual basis. Countries reporting data from household surveys, may report a new value every 3-5 years, according to their data collection schedule. Data reported from routine administrative source are regularly available on an annual basis.

3.d. Data release calendar

Country reported data and global and regional estimates are published annually; in February by UNICEF in the data website www.data.unicef.org (3) and by the World Health Organization in May in the World Health Statistics Report (<http://www.who.int/whosis/whostat/en/>) and the WHO Global Health Observatory (<https://apps.who.int/gho/data/node.main>). UNICEF also reports this indicator in the State of the World's Children report which is on a bi-annual reporting schedule.

3.e. Data providers

Ministries of Health and National Statistical Offices, either through household surveys or routine sources.

3.f. Data compilers

United Nations Children's Fund (UNICEF), World Health Organization (WHO).

3.g. Institutional mandate

UNICEF and WHO are co-custodians for the compilation and reporting of this indicator.

4. Other methodological considerations

4.a. Rationale

Having a skilled health care provider at the time of childbirth is an important lifesaving intervention for both women and newborns. Not having access to this key assistance is detrimental to women's and newborns health because it could cause the death of the women and/or the newborn or long lasting morbidity. Achieving universal coverage for this indicator is therefore essential for reducing maternal and newborn mortality.

4.b. Comment and limitations

Births attended by skilled health personnel is an indicator of health care utilization. It is a measure of the health system's functioning and potential to provide adequate coverage for childbirth. On its own, however, this indicator does not provide insight into the availability or accessibility of services, for example in cases where emergency care is needed. Neither does this indicator capture the quality of care received.

Data collection and data interpretation in many countries is challenged by lack of guidelines, standardization of professional titles and functions of the health care provider, and in some countries by task-shifting. In addition, many countries have found that there are large gaps between international standards and the competencies of existing health care professionals providing childbirth care. Lack of training and an enabling environment often hinder evidence based management of common obstetric and neonatal complications.

The most commonly used denominator is the number of live births.

4.c. Method of computation

Numerator:

Number of births attended by skilled health personnel (doctor, nurse or midwife) trained in providing quality obstetric care, including giving the necessary support and care to the mother and the newborn during childbirth and immediate postpartum period

Denominator: The total number of live births in the same period.

4.d. Validation

As part of the data harmonization process an annual country consultation conducted by UNICEF. Country inputs are reviewed and assessed jointly with WHO. During the process SDG country focal points are contacted for updating and verifying values included in the database and obtaining new sources of data. The national categories of skilled health personnel are verified, and the estimates for some countries may include additional categories of trained personnel beyond doctor, nurse, and midwife. This process serves as validation of the reported values.

Furthermore, with regard to data obtained from surveys, the validity of such data depends on the correct identification by the women of the credentials of the person attending the delivery, which may not be obvious in certain countries.

4.e. Adjustments

In cases where reporting of skilled categories is not consistent with previous years or with categories considered skilled at country level, reported values may be adjusted. When this is done, the process is consulted with countries.

4.f. Treatment of missing values (i) at country level and (ii) at regional level

- **At country level**

There is no treatment of missing values at country level. If value is missing for a given year, then there is no reporting of that value.

- **At regional and global levels**

Missing values are not imputed for regional and global levels. For the latest reported time period, the latest available year in the year range is used for the calculation of regional and global average

4.g. Regional aggregations

Regional and global estimates are calculated using weighed averages. Annual number of births from United Nations Population Division, World Population Prospects (3) are used as weighing indicator. Regional values are calculated for a reference year, including a range of 4-5 years for each reference year or year range. For example, for 2020, the latest year available for the period 2014-2020 was used.

4.h. Methods and guidance available to countries for the compilation of the data at the national level

Definition of skilled health personnel varies between countries. The proportion of births attended by skilled health personnel is calculated as the number of births attended by skilled health personnel (doctors, nurses or midwives) expressed as a proportion of the number of live births in the same period.

Births attended by skilled health personnel = (number of births attended by skilled health personnel)/(total number of live births) x 100.

In household surveys, such as DHS, MICS and RHS, the respondent is asked about the most recent birth and who helped during childbirth for a period up to five years before the interview. For consistency of reporting, survey customization teams in country are encouraged to review categories of health care providers reported on the previous surveys and ensure comparability.

Service/facility records could be used where a high proportion of births occur in health facilities and are therefore recorded.

4.i. Quality management

Data are reported to UNICEF on an annual basis. Values are reviewed and assessed to make sure that reported indicator complies with standard definition and methodology.

4.j Quality assurance

As part of the data harmonization process an annual country consultation process is conducted by UNICEF. Country inputs are reviewed and assessed jointly with WHO. During the process SDG country focal points are contacted for updating and verifying values included in the data bases and obtaining new sources of data. The national categories of skilled health personnel are verified, and the reported data for some countries may include additional categories of trained personnel beyond doctor, nurse, and midwife.

4.k Quality assessment

5. Data availability and disaggregation

Data availability:

Data are available for over 170 countries.

The lag between the reference year and actual production of data series depends on the availability of the household survey for each country.

Time series:

2000-2020

Disaggregation:

For this indicator, when data are reported from household surveys, disaggregation is available for various socio-economic characteristics including age of the mother, residence (urban/rural), household wealth (quintiles), education level of the mother, maternal age, geographic regions. When data are reported from administrative sources, disaggregation is more limited and tend to include only residence.

6. Comparability / deviation from international standards

Sources of discrepancies:

Discrepancies are possible if there are national figures compiled at the health facility level. These would differ from the global figures, which are typically based on survey data collected at the household level. In terms of survey data, some survey reports may present a total percentage of births attended by a skilled health professional that does not conform to the SDG definition (e.g., total includes provider that

is not considered skilled, such as a community health worker). In that case, the proportion of childbirths by a physician, nurse, or a midwife are totalled, consulted with the country and included in the global database as the SDG estimate.

In some countries where the indicator on skilled health personnel is not actively reported, birth in a health facility (institutional births) is used as a proxy indicator. This is frequent in countries in the Latin America region, in European and Central Asian regions, where the proportion of births attended by health professionals is very high. Nonetheless, it should be noted that institutional births may underestimate the percentage of births assisted by skilled health professionals, particularly in cases where home births -assisted by skilled health professionals -are prevalent.
